

<p align="center"><b>Ahsanullah University of Science and Technology</b>  <b>Course Title: Object Oriented Programming Lab</b>  <b>Course Number: CSE1206</b></p>
---

**Group: A1**

	<b>Marks</b>
1. Project Name: TestEmployee (contains the main method) Create 2 separate classes: <b>Developer</b> , <b>HROfficer</b>	<b>1</b>
2. Design the <b>Developer</b> class: a. <b>private</b> variables: <b>totalProjects</b> (int) , <b>totalMonths</b> (int) b. Create the parameterized constructor. c. Declare the getter setter methods for the private variables.	<b>1+2+4 =7</b>
3. Design the <b>HROfficer</b> class: a. Create variable: <b>public Developer devObj;</b> b. Create the constructor taking Developer as the parameter.	<b>1+2= 3</b>
4. Inside <b>HROfficer</b> class create a <b>void</b> method named: <b>checkPerformance()</b> Here calculate the final performance of a developer using the formula: <b>totalProjects * totalMonths + 100</b> Then print this performance result inside this method. You will need to use the variable <b>devObj</b> of Developer class and the getter methods.	<b>2</b>
5. Create objects of <b>Developer</b> and <b>HROfficer</b> classes inside the TestEmployee class. Initialize using the parameterized constructors. Also call the <b>checkPerformance()</b> method.  <b>*Extra marks if you take user input.</b>	<b>2+1 = 3</b>
6. Inside the <b>checkPerformance()</b> method, check the final performance as follows:  If this final performance is an <b>odd number</b> then print "Developer's performance is good" Otherwise print "Developer's performance is bad"	<b>4</b>

**Total: 20**

**You can use Math.pow(value, power)**

**Please Go the Next Page**

Sample Input 1	Sample Output
Total Projects : 5 Total Months : 18	Performance result is: 190 Developer's performance is bad

Sample Input 2	Sample Output
Total Projects : 3 Total Months : 11	Performance result is: 133 Developer's performance is good
